EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER, AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

UNLESS OTHERWISE AGREED IN WRITING BY INTEL, THE INTEL PRODUCTS ARE NOT DESIGNED NOR INTENDED FOR ANY APPLICATION IN WHICH THE FAILURE OF THE INTEL PRODUCT COULD CREATE A SITUATION WHERE PERSONAL INJURY OR DEATH MAY OCCUR.

Intel may make changes to specifications and product descriptions at any time, without notice.

Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them.

The products described in this document may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

^AIntel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See http://www.intel.com/products/processor_number for details. Over time processor numbers will increment based on changes in clock, speed, cache, FSB, or other features, and increments are not intended to represent proportional or quantitative increases in any particular feature. Current roadmap processor number progression is not necessarily representative of future roadmaps. See www.intel.com/products/processor_number for details.

Intel[®] Active Management Technology requires the computer system to have an Intel(R) AMT-enabled chipset, network hardware and software, as well as connection with a power source and a corporate network connection. Setup requires configuration by the purchaser and may require scripting with the management console or further integration into existing security frameworks to enable certain functionality. It may also require modifications of implementation of new business processes. With regard to notebooks, Intel AMT may not be available or certain capabilities may be limited over a host OS-based VPN or when connecting wirelessly, on battery power, sleeping, hibernating or powered off. For more information, see www.intel.com/ technology/platform-technology/intel-amt/

Intel® Trusted Execution Technology (Intel® TXT) requires a computer system with Intel® Virtualization Technology (Intel® Virtualization Technology (Intel® VT-x) and Intel® Virtualization Technology for Directed I/O (Intel® VT-d)), a Intel TXT-enabled processor, chipset, BIOS, Authenticated Code Modules and an Intel TXT-compatible measured launched environment (MLE). The MLE could consist of a virtual machine monitor, an OS or an application. In addition, Intel TXT requires the system to contain a TPM v1.2, as defined by the Trusted Computing Group and specific software for some uses. For more information, see http://www.intel.com/technology/security

Intel[®] Virtualization Technology requires a computer system with an enabled Intel[®] processor, BIOS, virtual machine monitor (VMM) and, for some uses, certain computer system software enabled for it. Functionality, performance or other benefits will vary depending on hardware and software configurations and may require a BIOS update. Software applications may not be compatible with all operating systems. Please check with your application vendor.

Warning: Altering clock frequency and/or voltage may (i) reduce system stability and useful life of the system and processor; (ii) cause the processor and other system components to fail; (iii) cause reductions in system performance; (iv) cause additional heat or other damage; and (v) affect system data integrity. Intel has not tested, and does not warranty, the operation of the processor beyond its specifications.

* Intel® Turbo Boost Technology requires a PC with a processor with Intel Turbo Boost Technology capability. Intel Turbo Boost Technology performance varies depending on hardware, software and overall system configuration. Check with your PC manufacturer on whether your system delivers Intel Turbo Boost Technology. For more information, see http://www.intel.com/technology/turboboost

Hyper-threading Technology requires a computer system with a processor supporting HT Technology and an HT Technology-enabled chipset, BIOS, and operating system. Performance will vary depending on the specific hardware and software you use. For more information including details on which processors support HT Technology, see http://www.intel.com/info/hyperthreading.

64-bit computing on Intel architecture requires a computer system with a processor, chipset, BIOS, operating system, device drivers and applications enabled for Intel[®] 64 architecture. Performance will vary depending on your hardware and software configurations. Consult with your system vendor for more information.

Enabling Execute Disable Bit functionality requires a PC with a processor with Execute Disable Bit capability and a supporting operating system. Check with your PC manufacturer on whether your system delivers Execute Disable Bit functionality.

Enhanced Intel SpeedStep[®] Technology for specified units of this processor available Q2/06. See the Processor Spec Finder at http://processorfinder.intel.com or contact your Intel representative for more information.

§§

1 Introduction

The Intel[®] Xeon[®] processor 3400 series are the next generation of 64-bit, multi-core processors built on 45-nanometer process technology. Based on the low-power/high-performance Intel microarchitecture, the processor is designed for a two-chip platform, instead of the traditional three-chip platforms (processor, (G)MCH, and ICH). The two-chip platform consists of a processor and Platform Controller Hub (PCH) and enables higher performance, easier validation, and improved x-y footprint. The Intel[®] 3400 Series Chipset components for servers and workstations are the PCH. The Intel[®] Xeon[®] processor 3400 series is intended for UP server and workstation platforms.

This document provides DC electrical specifications, signal integrity, differential signaling specifications, pinout and signal definitions, interface functional descriptions, and additional feature information pertinent to the implementation and operation of the processor on its respective platform.

- *Note:* Throughout this document, the Intel[®] Xeon[®] processor 3400 series may be referred to as "processor".
- *Note:* Throughout this document, the Intel[®] Xeon[®] processor 3400 series refers to the Intel[®] Xeon[®] X3480, X3470, X3460, X3450, X3440, X3430, and L3426 processors.
- *Note:* Througout this document, the Intel[®] 3400 Series Chipset Platform Controller Hub may be referred to as "PCH".
- *Note:* Some processor features are not available on all platforms. Refer to the processor specification update for details.

Included in this family of processors is an integrated memory controller (IMC) and integrated I/O (IIO) (such as PCI Express* and DMI) on a single silicon die. This single die solution is known as a monolithic processor. For specific features supported on individual Intel Xeon processor 3400 series SKUs, refer to the *Intel[®] Xeon[®] Processor 3400 Series Specification Update*. Figure 1-1 shows an example server platform block diagram.

Figure 1-1. Intel[®] Xeon[®] Processor 3400 Series Platform Diagram

1.1 **Processor Feature Details**

- Four cores
- A 32-KB instruction and 32-KB data first-level cache (L1) for each core
- A 256-KB shared instruction/data second-level cache (L2) for each core
- 8-MB shared instruction/data last-level cache (L3), shared among all cores

1.1.1 **Supported Technologies**

- Intel[®] Virtualization Technology for Directed I/O (Intel[®] VT-d)
- Intel[®] Virtualization Technology (Intel[®] VT-x)
- Intel[®] Trusted Execution Technology (Intel[®] TXT)
- Intel Active Management Technology 6.0 (Intel 3450 Chipset platform only)
- Intel[®] Streaming SIMD Extensions 4.1 (Intel[®] SSE4.1)
- Intel[®] Streaming SIMD Extensions 4.2 (Intel[®] SSE4.2)
- Intel[®] Hyper-Threading Technology
- Intel[®] 64 Architecture
- Execute Disable Bit
- Intel[®] Turbo Boost Technology
- Note: Some technologies may not be enabled on all processor SKUs. Refer to the processor specification update for details.
- Intel[®] Active Management Technology 6.0 is not supported on the Intel Xeon processor Note: 3400 series for Intel 3400 and 3420 Chipset Platforms.

Interfaces 1.2

1.2.1 System Memory Support

Intel[®] Xeon[®] Processor 3400 Series Supported Memory Summary Table 1-1.

Platform	Memory Type	# of Channels	DI MMs/ Channel	Transfer Rate (MT/s)	Notes
Intel 3450 Chipset Platform	DDR3: Non-ECC Unbuffered	1 or 2	1 or 2	1066, 1333	2
inter 5450 empset hattorn	DDR3: ECC Unbuffered	1 or 2	1 or 2	1066, 1333	2
Intel 3400 and 3420 Chipset	DDR3: ECC Registered DIMM	1 or 2	Up to 3	800, 1066, 1333	1
Platforms	DDR3: ECC Unbuffered DIMM	1 or 2	1 or 2	1066, 1333	1

Notes:

Non-ECC DIMMs are not supported. Mixing of non-ECC and ECC DIMMs is not supported. Mixing of non-ECC and ECC DIMMs is not supported. Registered DIMMs are not supported. 1.

System memory features include:

- · Data burst length of eight for all memory organization modes
- 64-bit wide channels
- DDR3 I/O Voltage of 1.5 V
- Maximum memory bandwidth of 10.6 GB/s in single-channel mode or 21 GB/s in dual-channel mode assuming DDR3 1333 MT/s
- 1-Gb and 2-Gb DDR3 DRAM technologies are supported.
- Using 2-Gb device technologies, the largest memory capacity possible is 16 GB for UDIMMs (assuming Dual Channel Mode with a four dual rank unbuffered, non-ECC DIMM memory configuration), and 32 GB for RDIMMs (assuming Dual Channel Mode with a four quad-rank registered DIMM memory configuration)
- Up to 64 simultaneous open pages, 32 per channel (assuming 8 ranks of 8 bank devices)
- Command launch modes of 1n/2n
- Intel[®] Fast Memory Access (Intel[®] FMA)
 - Just-in-Time Command Scheduling
 - Command Overlap
 - Out-of-Order Scheduling

1.2.2 PCI Express*

- The processor PCI Express* port(s) are fully-compliant with the PCI Express Base Specification, Revision 2.0.
- Intel[®] Xeon[®] processor 3400 series with the Intel[®] 3450 Chipset supports:
 - One 16-lane PCI Express port intended for graphics attach.
 - Two 8-lane PCI Express ports for graphics or I/O.
- $\mbox{Intel}^{\mbox{$\mathbb{8}$}}$ Xeon $\mbox{$\mathbb{8}$}$ processor 3400 series with the Intel 3420 Chipset supports:
 - One 16-Iane PCI Express port intended for graphics or I/O.
 - Two 8-lane PCI Express ports intended for I/O.
 - Four 4-lane PCI Express ports intended for I/O.
- Intel $^{\ensuremath{\mathbb{R}}}$ Xeon $^{\ensuremath{\mathbb{R}}}$ processor 3400 series with the Intel 3400 Chipset supports:
 - Two 8-lane PCI Express ports intended for I/O.
 - Four 4-lane PCI Express ports intended for I/O.
- PCI Express port 0 is mapped to PCI Device 3.
- PCI Express port 1 is mapped to PCI Device 5.
- The port may negotiate down to narrower widths.
 - Support for x16/x8/x4/x1 widths for a single PCI Express mode.
- 2.5 GT/s and 5.0 GT/s PCI Express frequencies are supported.
- Either port can be configured independently as 2.5 GT/s or 5.0 GT/s.
- Raw bit-rate on the data pins of 5.0 GB/s, resulting in a real bandwidth per pair of 500 MB/s given the 8b/10b encoding used to transmit data across this interface. This also does not account for packet overhead and link maintenance.
- Maximum theoretical bandwidth on interface of 8 GB/s in each direction simultaneously, for an aggregate of 16 GB/s for x16.
- Hierarchical PCI-compliant configuration mechanism for downstream devices.
- Traditional PCI style traffic (asynchronous snooped, PCI ordering).

- PCI Express extended configuration space. The first 256 bytes of configuration space aliases directly to the PCI Compatibility configuration space. The remaining portion of the fixed 4-KB block of memory-mapped space above that (starting at 100h) is known as extended configuration space.
- PCI Express Enhanced Access Mechanism. Accessing the device configuration space in a flat memory mapped fashion.
- Automatic discovery, negotiation, and training of link out of reset.
- Traditional AGP style traffic (asynchronous non-snooped, PCI-X* Relaxed ordering).
- Peer segment destination posted write traffic (no peer-to-peer read traffic) in Virtual Channel 0:
 - PCI Express Port 0 -> PCI Express Port 1
 - PCI Express Port 1 -> PCI Express Port 0
 - DMI -> PCI Express Port 0
 - DMI -> PCI Express Port 1
 - PCI Express Port 1 -> DMI
 - PCI Express Port 0 -> DMI
- 64-bit downstream address format, but the processor never generates an address above 64 GB (Bits 63:36 will always be zeros).
- 64-bit upstream address format, but the processor responds to upstream read transactions to addresses above 64 GB (addresses where any of Bits 63:36 are nonzero) with an Unsupported Request response. Upstream write transactions to addresses above 64 GB will be dropped.
- Re-issues Configuration cycles that have been previously completed with the Configuration Retry status.
- PCI Express reference clock is 100-MHz differential clock.
- Power Management Event (PME) functions.
- Dynamic lane numbering reversal as defined by the PCI Express Base Specification.
- Dynamic frequency change capability (2.5 GT/s 5.0 GT/s)
- Dynamic width capability
- Message Signaled Interrupt (MSI and MSI-X) messages
- Polarity inversion

1.2.3 Direct Media Interface (DMI)

- Four lanes in each direction.
- 2.5 GT/s point-to-point DMI interface to PCH is supported.
- Raw bit-rate on the data pins of 2.5 GB/s, resulting in a real bandwidth per pair of 250 MB/s given the 8b/10b encoding used to transmit data across this interface. Does not account for packet overhead and link maintenance.
- Maximum theoretical bandwidth on interface of 1 GB/s in each direction simultaneously, for an aggregate of 2 GB/s when DMI x4.
- Shares 100-MHz PCI Express reference clock.
- 64-bit downstream address format, but the processor never generates an address above 64 GB (Bits 63:36 will always be zeros).
- 64-bit upstream address format, but the processor responds to upstream read transactions to addresses above 64 GB (addresses where any of Bits 63:36 are nonzero) with an Unsupported Request response. Upstream write transactions to addresses above 64 GB will be dropped.

- Supports the following traffic types to or from the PCH
 - DMI -> PCI Express Port 0 write traffic
 - DMI -> PCI Express Port 1 write traffic
 - DMI -> DRAM
 - DMI -> processor core (Virtual Legacy Wires (VLWs), Resetwarn, or MSIs only)
 Processor core -> DMI
- APIC and MSI interrupt messaging support
 Massage Signaled Interrupt (MSI and MSI
 - Message Signaled Interrupt (MSI and MSI-X) messages
- Downstream SMI, SCI, and SERR error indication
- Legacy support for ISA regime protocol (PHOLD/PHOLDA) required for parallel port DMA, floppy drive, and LPC bus masters
- DC coupling no capacitors between the processor and the PCH
- Polarity inversion
- PCH end-to-end lane reversal across the link
- Supports Half Swing "low-power/low-voltage" and Full Swing "high-power/high-voltage" modes

1.2.4 Platform Environment Control Interface (PECI)

The PECI is a one-wire interface that provides a communication channel between processor and a PECI master, usually the PCH.

1.3 Power Management Support

1.3.1 Processor Core

- Full support of ACPI C-states as implemented by the following processor C-states:
 C0, C1, C1E, C3, C6
- Enhanced Intel SpeedStep[®] Technology

1.3.2 System

• S0, S1, S4, S5

1.3.3 Memory Controller

- Conditional self-refresh
- Dynamic power-down

1.3.4 PCI Express*

- LOs and L1 ASPM power management capability.
 - LOs not supported on the Intel Xeon $^{\mbox{\tiny B}}$ processor 3400 series when configured as PCI Express 4x4

1.4 Thermal Management Support

- Digital Thermal Sensor
- Intel[®] Adaptive Thermal Monitor
- THERMTRIP# and PROCHOT# support
- On-Demand Mode
- Memory Thermal Throttling
- External Thermal Sensor
- Fan Speed Control with DTS

1.5 Package

• The processor socket type is noted as LGA 1156. The package is a 37.5 x 37.5 mm Flip Chip Land Grid Array (FCLGA 1156).

1.6 Terminology

Term	Description
DDR3	Third generation Double Data Rate SDRAM memory technology
DP	Display Port*
DMA	Direct Memory Access
DMI	Direct Media Interface
DTS	Digital Thermal Sensor
ECC	Error Correction Code
Enhanced Intel SpeedStep [®] Technology	Technology that provides power management capabilities.
Execute Disable Bit	The Execute Disable bit allows memory to be marked as executable or non- executable, when combined with a supporting operating system. If code attempts to run in non-executable memory, the processor raises an error to the operating system. This feature can prevent some classes of viruses or worms that exploit buffer overrun vulnerabilities and can, thus, help improve the overall security of the system. See the <i>Intel® 64 and IA-32 Architectures Software Developer's Manuals</i> for more detailed information.
FCLGA	Flip Chip Land Grid Array
(G)MCH	Legacy component – Graphics Memory Controller Hub. Platforms using LGA 1156 processors do not use a (G)MCH component.
ІСН	The legacy I/O Controller Hub component that contains the main PCI interface, LPC interface, USB2, Serial ATA, and other I/O functions. It communicates with the legacy (G)MCH over a proprietary interconnect called DMI. Platforms using LGA 1156 processors do not use an ICH component.
IMC	Integrated Memory Controller
Intel [®] 64 Technology	64-bit memory extensions to the IA-32 architecture.
Intel [®] Hyper-Threading Technology	The processor supports Intel [®] Hyper-Threading Technology (Intel [®] HT Technology) that allows an execution core to function as two logical processors.
Intel [®] Turbo Boost Technology	Intel [®] Turbo Boost Technology is a feature that allows the processor core to opportunistically and automatically run faster than its rated operating frequency if it is operating below power, temperature, and current limits.
Intel [®] TXT	Intel [®] Trusted Execution Technology

Term	Description
Intel [®] VT-d	Intel [®] Virtualization Technology (Intel [®] VT) for Directed I/O. Intel VT-d is a hardware assist, under system software (Virtual Machine Manager or OS) control, for enabling I/O device virtualization. VT-d also brings robust security by providing protection from errant DMAs by using DMA remapping, a key feature of Intel VT-d.
Intel [®] Virtualization Technology	Processor virtualization which when used in conjunction with Virtual Machine Monitor software enables multiple, robust independent software environments inside a single platform.
ITPM	Integrated Trusted Platform Module
IOV	I/O Virtualization
LCD	Liquid Crystal Display
LVDS	Low Voltage Differential Signaling. A high speed, low power data transmission standard used for display connections to LCD panels.
NCTF	Non-Critical to Function: NCTF locations are typically redundant ground or non- critical reserved, so the loss of the solder joint continuity at end of life conditions will not affect the overall product functionality.
РСН	Platform Controller Hub. The new, 2009 chipset with centralized platform capabilities including the main I/O interfaces along with display connectivity, audio features, power management, manageability, security and storage features.
PECI	Platform Environment Control Interface
PEG	PCI Express* Graphics. External Graphics using PCI Express Architecture. A high- speed serial interface whose configuration is software compatible with the existing PCI specifications.
Processor	The 64-bit multi-core component (package)
Processor Core	The term "processor core" refers to Si die itself which can contain multiple execution cores. Each execution core has an instruction cache, data cache, and 256-KB L2 cache. All execution cores share the L3 cache.
Rank	A unit of DRAM corresponding to four to eight devices in parallel, ignoring ECC. These devices are usually, but not always, mounted on a single side of a DIMM.
SCI	System Control Interrupt. Used in ACPI protocol.
Storage Conditions	A non-operational state. The processor may be installed in a platform, in a tray, or loose. Processors may be sealed in packaging or exposed to free air. Under these conditions, processor landings should not be connected to any supply voltages, have any I/Os biased or receive any clocks. Upon exposure to "free air" (that is, unsealed packaging or a device removed from packaging material), the processor must be handled in accordance with moisture sensitivity labeling (MSL) as indicated on the packaging material.
TAC	Thermal Averaging Constant
TDP	Thermal Design Power
TLP	Transaction Layer Packet
ТОМ	Top of Memory
TTM	Time-To-Market
V _{CC}	Processor core power rail
V _{SS}	Processor ground
V _{TT}	L3 shared cache, memory controller, and processor I/O power rail
V _{DDQ}	DDR3 power rail
VLD	Variable Length Decoding
x1	Refers to a Link or Port with one Physical Lane
x4	Refers to a Link or Port with four Physical Lanes
x8	Refers to a Link or Port with eight Physical Lanes
x16	Refers to a Link or Port with sixteen Physical Lanes

Introduction

2 Interfaces

This chapter describes the interfaces supported by the processor.

2.1 System Memory Interface

2.1.1 System Memory Technology Supported

The Integrated Memory Controller (IMC) supports DDR3 protocols with two independent, 64-bit wide channels. Refer to Section 1.2.1 for details on the type of memory supported.

- Supported DIMM Types
 - Unbuffered DIMMs-1066 MT/s (PC3-8500), and 1333 MT/s (PC3-10600)
 - Registered DIMMs-1066 MT/s (PC3-8500), and 1333 MT/s (PC3-10600)
- Intel 3450 Chipset platforms DDR3 DIMM Modules
 - Raw Card A-Single Sided x8 unbuffered non-ECC
 - Raw Card B-Double Sided x8 unbuffered non-ECC
 - Raw Card C—Single Sided x16 unbuffered non-ECC
 - Raw Card D-Single Sided x8 unbuffered ECC
 - Raw Card E-Double Sided x8 unbuffered ECC
- Intel 3400 and 3420 Chipset platforms DDR3 DIMM Modules
 - Raw Card D-Single Sided x8 unbuffered ECC
 - Raw Card E-Double Sided x8 unbuffered ECC
 - Raw Card A—Single Sided x8 registered ECC
 - Raw Card B-Double Sided x8 registered ECC
 - Raw Card G-Quad Rank x8 registered ECC
 - Raw Card H-Quad Rank Stacked x8 registered ECC
- DDR3 DRAM Device Technology
 - Unbuffered—1-Gb and 2-Gb DDR3 DRAM Device technologies and addressing are supported (as detailed in Table 2-1).
 - Registered—1-Gb and 2-Gb DDR3 DRAM Device technologies and addressing are supported (as detailed in Table 2-1).

Table 2-1. Supported DIMM Module Configurations

Note: DIMM module support is based on availability and is subject to change.

2.1.2 System Memory Timing Support

The IMC supports the following DDR3 Speed Bin, CAS Write Latency (CWL), and command signal mode timings on the main memory interface:

- $t_{CL} = CAS Latency$
- t_{RCD} = Activate Command to READ or WRITE Command delay
- t_{RP} = PRECHARGE Command Period
- CWL = CAS Write Latency
- Command Signal modes = 1N indicates a new command may be issued every clock and 2N indicates a new command may be issued every 2 clocks. Command launch mode programming depends on the transfer rate and memory configuration.

DDR3 System Memory Timing Support Table 2-2.

Transfer Rate (MT/s)	t _{CL} (t _{CK})	t _{RCD} (t _{CK})	t _{RP} (t _{CK})	CWL (t _{CK})	Unbuffered DIMM CMD Mode	Registered DIMM CMD Mode	Notes		
	6	6	6	5	N/A	1N Only	4		
1066	7	7	7	6	6	6	See Note 1, 2, 3	1N Only	4
1000	8	8	8			in only	-		
	8	8	8				4		
1333	9	9	9	7	7	7	7 See Note 1, 2, 3	1N Only	4
	10	10	10				4		

Note:

1.

- 2.
- Two Un-buffered DIMM Memory Configurations = 2N Command Mode at 1067/1333 MHz One Un-buffered DIMM Memory Configurations = 1N Command Mode at 1067/1333 MHz Both Channel A and B will run at same Command Mode based on the slowest mode enabled relative to the 3 memory configurations populated in both channels. For example, if Channel A has both DIMM connectors populated (2N CMD Mode) and Channel B has only one DIMM connector populated (1N CMD Mode) then 2N CMD mode would be enabled for both channels.
- System Memory timing support is based on availability and is subject to change. 4.

2.1.3 System Memory Organization Modes

The IMC supports two memory organization modes, single-channel and dual-channel. Depending upon how the DIMM Modules are populated in each memory channel, a number of different configurations can exist.

2.1.3.1 Single-Channel Mode

In this mode, all memory cycles are directed to a single-channel. Single-channel mode is used when either Channel A or Channel B DIMM connectors are populated, but not both.

2.1.3.2 Dual-Channel Mode—Intel[®] Flex Memory Technology Mode

The IMC supports Intel Flex Memory Technology mode. This mode combines the advantages of the Dual-Channel Symmetric (Interleaved) and Dual-Channel Asymmetric Modes. Memory is divided into a symmetric and a asymmetric zone. The symmetric zone starts at the lowest address in each channel and is contiguous until the asymmetric zone begins or until the top address of the channel with the smaller capacity is reached. In this mode, the system runs with one zone of dual-channel mode and one zone of single-channel mode, simultaneously, across the whole memory array.

Figure 2-1. Intel[®] Flex Memory Technology Operation

2.1.3.2.1 Dual-Channel Symmetric Mode

Dual-Channel Symmetric mode, also known as interleaved mode, provides maximum performance on real world applications. Addresses are ping-ponged between the channels after each cache line (64-byte boundary). If there are two requests, and the second request is to an address on the opposite channel from the first, that request can be sent before data from the first request has returned. If two consecutive cache lines are requested, both may be retrieved simultaneously, since they are ensured to be on opposite channels. Use Dual-Channel Symmetric mode when both Channel A and Channel B DIMM connectors are populated in any order, with the total amount of memory in each channel being the same.

When both channels are populated with the same memory capacity and the boundary between the dual channel zone and the single channel zone is the top of memory, IMC operates completely in Dual-Channel Symmetric mode.

Note: The DRAM device technology and width may vary from one channel to the other.

2.1.3.2.2 Dual-Channel Asymmetric Mode

This mode trades performance for system design flexibility. Unlike the previous mode, addresses start at the bottom of Channel A and stay there until the end of the highest rank in Channel A, and then addresses continue from the bottom of Channel B to the top. Real world applications are unlikely to make requests that alternate between addresses that sit on opposite channels with this memory organization, so in most cases, bandwidth is limited to a single channel.

This mode is used when Intel Flex Memory Technology is disabled and both Channel A and Channel B DIMM connectors are populated in any order with the total amount of memory in each channel being different.

Figure 2-2. Dual-Channel Symmetric (Interleaved) and Dual-Channel Asymmetric Modes

2.1.4 Rules for Populating Memory Slots

In all modes, the frequency of system memory is the lowest frequency of all memory modules placed in the system, as determined through the SPD registers on the memory modules. The system memory controller supports one or two DIMM connectors per channel for unbuffered DIMMs or up to three DIMM connectors per channel for registered DIMMs.For dual-channel modes, both channels must have at least one DIMM connector populated and for single-channel mode only a single-channel may have one or more DIMM connectors populated.

Note: DIMMO must always be populated within any memory configuration. DIMMO is the furthest DIMM within a channel and is identified by the CS#[1:0], ODT[1:0], and CKE[1:0] signals.

2.1.5 Technology Enhancements of Intel[®] Fast Memory Access (Intel[®] FMA)

The following sections describe the Just-in-Time Scheduling, Command Overlap, and Out-of-Order Scheduling Intel FMA technology enhancements.

2.1.5.1 Just-in-Time Command Scheduling

The memory controller has an advanced command scheduler where all pending requests are examined simultaneously to determine the most efficient request to be issued next. The most efficient request is picked from all pending requests and issued to system memory Just-in-Time to make optimal use of Command Overlapping. Thus, instead of having all memory access requests go individually through an arbitration mechanism forcing requests to be executed one at a time, they can be started without interfering with the current request allowing for concurrent issuing of requests. This allows for optimized bandwidth and reduced latency while maintaining appropriate command spacing to meet system memory protocol.

2.1.5.2 Command Overlap

Command Overlap allows the insertion of the DRAM commands between the Activate, Precharge, and Read/Write commands normally used, as long as the inserted commands do not affect the currently executing command. Multiple commands can be issued in an overlapping manner, increasing the efficiency of system memory protocol.

2.1.5.3 Out-of-Order Scheduling

While leveraging the Just-in-Time Scheduling and Command Overlap enhancements, the IMC continuously monitors pending requests to system memory for the best use of bandwidth and reduction of latency. If there are multiple requests to the same open page, these requests would be launched in a back to back manner to make optimum use of the open memory page. This ability to reorder requests on the fly allows the IMC to further reduce latency and increase bandwidth efficiency.

2.1.6 System Memory Pre-Charge Power Down Support Details

The IMC supports and enables the following DDR3 DRAM Device pre-charge power down DLL controls during a pre-charge power down.

- Slow Exit is where the DRAM device DLL is disabled after entering pre-charge power down
- Fast Exit is where the DRAM device DLLs are maintained after entering pre-charge power down

DIMM per Channel Configuration	DIMM Туре	Precharge Power Down Slow/Fast Exit
One	Unbuffered DIMM	Slow Exit
Two	Unbuffered DIMM	Fast Exit
One	Registered DIMM Raw Cards A, B, D, or E	Slow Exit
Two or Three	Registered DIMM Raw Cards A, B, D, or E	Fast Exit
One or Two	Registered DIMM Raw Cards G or H	Fast Exit

Table 2-3. System Memory Pre-Charge Power Down Support

2.2 PCI Express* Interface

This section describes the PCI Express interface capabilities of the processor. See the *PCI Express Base Specification* for details of PCI Express.

The number of PCI Express controllers available is dependent on the platform:

- Intel Xeon processor 3400 series with the Intel 3450 Chipset: 1 x16 PCI Express Graphics or 2x8 PCI Express Graphics are supported.
- Intel Xeon processor 3400 series with Intel 3400 and 3420 Chipset: 1 x16 PCI Express I/O, 2 x8 PCI Express I/O, or 4 x4 PCI Express I/O are supported.

2.2.1 PCI Express* Architecture

Compatibility with the PCI addressing model is maintained to ensure that all existing applications and drivers operate unchanged.

The PCI Express configuration uses standard mechanisms as defined in the PCI Plugand-Play specification. The initial recovered clock speed of 1.25 GHz results in 2.5 Gb/s/direction which provides a 250-MB/s communications channel in each direction (500 MB/s total). That is close to twice the data rate of classic PCI. The fact that 8b/10b encoding is used accounts for the 250 MB/s where quick calculations would imply 300 MB/s. The PCI Express ports support 5.0 GT/s speed as well. Operating at 5.0 GT/s results in twice as much bandwidth per lane as compared to 2.5 GT/s operation. When operating with more than one PCI Express controller, each controller can be operating at either 2.5 GT/s or 5.0 GT/s.

The PCI Express architecture is specified in three layers: Transaction Layer, Data Link Layer, and Physical Layer. The partitioning in the component is not necessarily along these same boundaries. Refer to Figure 2-3 for the PCI Express Layering Diagram.

Figure 2-3. PCI Express* Layering Diagram

PCI Express uses packets to communicate information between components. Packets are formed in the Transaction and Data Link Layers to carry the information from the transmitting component to the receiving component. As the transmitted packets flow through the other layers, they are extended with additional information necessary to handle packets at those layers. At the receiving side the reverse process occurs and

packets get transformed from their Physical Layer representation to the Data Link Layer representation and finally (for Transaction Layer Packets) to the form that can be processed by the Transaction Layer of the receiving device.

2.2.1.1 Transaction Layer

The upper layer of the PCI Express architecture is the Transaction Layer. The Transaction Layer's primary responsibility is the assembly and disassembly of Transaction Layer Packets (TLPs). TLPs are used to communicate transactions, such as read and write, as well as certain types of events. The Transaction Layer also manages flow control of TLPs.

2.2.1.2 Data Link Layer

The middle layer in the PCI Express stack, the Data Link Layer, serves as an intermediate stage between the Transaction Layer and the Physical Layer. Responsibilities of the Data Link Layer include link management, error detection, and error correction.

The transmission side of the Data Link Layer accepts TLPs assembled by the Transaction Layer, calculates and applies data protection code and TLP sequence number, and submits them to the Physical Layer for transmission across the Link. The receiving Data Link Layer is responsible for checking the integrity of received TLPs and for submitting them to the Transaction Layer for further processing. On detection of TLP error(s), this layer is responsible for requesting retransmission of TLPs until information is correctly received, or the Link is determined to have failed. The Data Link Layer also generates and consumes packets that are used for Link management functions.

2.2.1.3 Physical Layer

The Physical Layer includes all circuitry for interface operation, including driver and input buffers, parallel-to-serial and serial-to-parallel conversion, PLL(s), and impedance matching circuitry. It also includes logical functions related to interface initialization and maintenance. The Physical Layer exchanges data with the Data Link Layer in an implementation-specific format, and is responsible for converting this to an appropriate serialized format and transmitting it across the PCI Express Link at a frequency and width compatible with the remote device.

2.2.2 PCI Express* Configuration Mechanism

The PCI Express (external graphics) link is mapped through a PCI-to-PCI bridge structure.

Figure 2-5. PCI Express* Related Register Structures in Processor

PCI Express extends the configuration space to 4096 bytes per-device/function, as compared to 256 bytes allowed by the Conventional PCI Specification. PCI Express configuration space is divided into a PCI-compatible region (consisting of the first 256 B of a logical device's configuration space) and an extended PCI Express region (consisting of the remaining configuration space). The PCI-compatible region can be accessed using either the mechanisms defined in the PCI specification or using the enhanced PCI Express configuration access mechanism described in the PCI Express Enhanced Configuration Mechanism section.

The PCI Express Host Bridge is required to translate the memory-mapped PCI Express configuration space accesses from the host processor to PCI Express configuration cycles. To maintain compatibility with PCI configuration addressing mechanisms, it is recommended that system software access the enhanced configuration space using 32-bit operations (32-bit aligned) only.

See the *PCI Express Base Specification* for details of both the PCI-compatible and PCI Express Enhanced configuration mechanisms and transaction rules.

2.2.3 PCI Express* Ports and Bifurcation

The PCI Express interface on the processor is a single 16 lane (x16) port that can also be configured at narrower widths. It may be bifurcated (refer to Table 6-5) and each port may train to narrower widths. The PCI Express port is designed to be compliant with the *PCI Express Base Specification rev 2.0*

2.2.3.1 PCI Express* Bifurcated Mode

When bifurcated, the signals that had previously been assigned to lanes 15:8 of the single x16 Primary port are reassigned to lanes 7:0 of the x8 Secondary port. This assignment applies whether the lane numbering is reversed or not. The controls for the Secondary port and the associated virtual PCI-to-PCI bridge can be found in PCI Device 5. Refer to Table 6-5 for port bifurcation configuration settings and supported configurations.

When the port is not bifurcated, Device 5 is hidden from the discovery mechanism used in PCI enumeration, such that configuration of the device is neither possible nor necessary.

2.3 Direct Media Interface (DMI)

DMI connects the processor and the PCH chip-to-chip. The DMI is similar to a four-lane PCI Express supporting up to 1 GB/s of bandwidth in each direction.

Note: Only DMI x4 configuration is supported.

2.3.1 DMI Error Flow

DMI can only generate SERR in response to errors—never SCI, SMI, MSI, PCI INT, or GPE. Any DMI related SERR activity is associated with Device 0.

2.3.2 Processor/PCH Compatibility Assumptions

The processor is compatible with the PCH and is not compatible with any previous (G)MCH or ICH products.

2.3.3 DMI Link Down

The DMI link going down is a fatal, unrecoverable error. If the DMI data link goes to data link down, after the link was up, then the DMI link hangs the system by not allowing the link to retrain to prevent data corruption. This is controlled by the PCH.

Downstream transactions that had been successfully transmitted across the link prior to the link going down may be processed as normal. No completions from downstream, non-posted transactions are returned upstream over the DMI link after a link down event.

2.4 Platform Environment Control Interface (PECI)

The PECI is a one-wire interface that provides a communication channel between processor and a PECI master, usually the PCH. The processor implements a PECI interface to:

- Allow communication of processor thermal and other information to the PECI master.
- Read averaged Digital Thermal Sensor (DTS) values for fan speed control.

2.5 Interface Clocking

2.5.1 Internal Clocking Requirements

Table 2-4. Processor Reference Clock Requirements

Reference Input Clocks	Input Frequency	Associated PLL

Interfaces

3 Technologies

3.1 Intel[®] Virtualization Technology

Intel Virtualization Technology (Intel VT) makes a single system appear as multiple independent systems to software. This allows multiple, independent operating systems to run simultaneously on a single system. Intel VT comprises technology components to support virtualization of platforms based on Intel architecture microprocessors and chipsets. Intel Virtualization Technology (Intel VT-x) added hardware support in the processor to improve the virtualization performance and robustness. Intel Virtualization Technology for Directed I/O (Intel VT-d) adds chipset hardware implementation to support and improve I/O virtualization performance and robustness.

Intel VT-x specifications and functional descriptions are included in the *Intel*[®] *64* and *IA-32* Architectures Software Developer's Manual, Volume 3B and is available at: http://www.intel.com/products/processor/manuals/index.htm.

The Intel VT-d spec and other VT documents can be referenced at: http://www.intel.com/technology/virtualization/index.htm.

3.1.1 Intel[®] VT-x Objectives

Intel VT-x provides hardware acceleration for virtualization of IA platforms. Virtual Machine Monitor (VMM) can use Intel VT-x features to provide improved reliable virtualized platforms. By using Intel VT-x, a VMM is:

- **Robust**—VMMs no longer need to use paravirtualization or binary translation. This means that they will be able to run off-the-shelf OSs and applications without any special steps.
- Enhanced—Intel VT enables VMMs to run 64-bit guest operating systems on IA x86 processors.
- **More reliable**—Due to the hardware support, VMMs can now be smaller, less complex, and more efficient. This improves reliability and availability and reduces the potential for software conflicts.
- **More secure**—The use of hardware transitions in the VMM strengthens the isolation of VMs and further prevents corruption of one VM from affecting others on the same system.

3.1.2 Intel[®] VT-x Features

The processor core supports the following Intel VT-x features:

- Extended Page Tables (EPT)
 - EPT is hardware assisted page table virtualization
 - It eliminates VM exits from guest OS to the VMM for shadow page-table maintenance
- Virtual Processor IDs (VPID)
 - Ability to assign a VM ID to tag processor core hardware structures (such as TLBs)
 - This avoids flushes on VM transitions to give a lower-cost VM transition time and an overall reduction in virtualization overhead.

- Guest Preemption Timer
 - Mechanism for a VMM to preempt the execution of a guest OS after an amount of time specified by the VMM. The VMM sets a timer value before entering a guest
 - The feature aids VMM developers in flexibility and Quality of Service (QoS) guarantees
- Descriptor-Table Exiting
 - Descriptor-table exiting allows a VMM to protect a guest OS from internal (malicious software based) attack by preventing relocation of key system data structures like IDT (interrupt descriptor table), GDT (global descriptor table), LDT (local descriptor table), and TSS (task segment selector).
 - A VMM using this feature can intercept (by a VM exit) attempts to relocate these data structures and prevent them from being tampered by malicious software.

3.1.3 Intel[®] VT-d Objectives

The key Intel VT-d objectives are domain-based isolation and hardware-based virtualization. A domain can be abstractly defined as an isolated environment in a platform to which a subset of host physical memory is allocated. Virtualization allows for the creation of one or more partitions on a single system. This could be multiple partitions in the same operating system, or there can be multiple operating system instances running on the same system—offering benefits such as system consolidation, legacy migration, activity partitioning, or security.

3.1.4 Intel[®] VT-d Features

The processor supports the following Intel VT-d features:

- 48-bit maximum guest address width and 36-bit maximum host address width for non-isoch traffic, in UP profiles
- 39-bit maximum guest address width and 36-bit maximum host address width for isoch (Intel High Definition Audio isoch) traffic
- Support for 4K page sizes only
- Support for register-based fault recording only (for single entry only) and support for MSI interrupts for faults
 - Support for fault collapsing based on Requester ID
- Support for both leaf and non-leaf caching
- Support for boot protection of default page table
- Support for non-caching of invalid page table entries
- Support for hardware based flushing of translated but pending writes and pending reads, on IOTLB invalidation
- · Support for page-selective IOTLB invalidation
- Support for queue-based invalidation interface
- Support for Intel VT-d read prefetching/snarfing (such as, translations within a cacheline are stored in an internal buffer for reuse for subsequent transactions)
- Support for ARI (Alternate Requester ID—a PCI SIG ECR for increasing the function number count in a PCI Express device) to support IOV devices

3.1.5 Intel[®] VT-d Features Not Supported

The following features are not supported by the processor with Intel VT-d:

- No support for PCISIG endpoint caching (ATS)
- No support for interrupt remapping
- No support for advance fault reporting
- No support for super pages
- No support for 1 or 2 level page walks for isoch remap engine and 1, 2, or 3 level walks for non-isoch remap engine
- No support for Intel VT-d translation bypass address range (such usage models need to be resolved with VMM help in setting up the page tables correctly)

3.2 Intel[®] Trusted Execution Technology (Intel[®] TXT)

Intel Trusted Execution Technology (Intel TXT) defines platform-level enhancements that provide the building blocks for creating trusted platforms.

The Intel TXT platform helps to provide the authenticity of the controlling environment such that those wishing to rely on the platform can make an appropriate trust decision. The Intel TXT platform determines the identity of the controlling environment by accurately measuring and verifying the controlling software.

Another aspect of the trust decision is the ability of the platform to resist attempts to change the controlling environment. The Intel TXT platform will resist attempts by software processes to change the controlling environment or bypass the bounds set by the controlling environment.

Intel TXT is a set of extensions designed to provide a measured and controlled launch of system software that will then establish a protected environment for itself and any additional software that it may execute.

These extensions enhance two areas:

- The launching of the Measured Launched Environment (MLE).
- The protection of the MLE from potential corruption.

The enhanced platform provides these launch and control interfaces using Safer Mode Extensions (SMX).

The SMX interface includes the following functions:

- Measured/Verified launch of the MLE.
- Mechanisms to ensure the above measurement is protected and stored in a secure location.
- Protection mechanisms that allow the MLE to control attempts to modify itself.

3.3 Intel[®] Hyper-Threading Technology

The processor supports Intel[®] Hyper-Threading Technology (Intel[®] HT Technology) that allows an execution core to function as two logical processors. While some execution resources such as caches, execution units, and buses are shared, each logical processor has its own architectural state with its own set of general-purpose registers and control registers. This feature must be enabled using the BIOS and requires operating system support.

Intel recommends enabling Hyper-Threading Technology with Microsoft Windows Vista*, Microsoft Windows* XP Professional/Windows* XP Home, and disabling Hyper-Threading Technology using the BIOS for all previous versions of Windows operating systems. For more information on Hyper-Threading Technology, see: http://www.intel.com/products/ht/hyperthreading_more.htm.

3.4 Intel[®] Turbo Boost Technology

Intel[®] Turbo Boost Technology is a feature that allows the processor core to opportunistically and automatically run faster than its rated operating frequency if it is operating below power, temperature, and current limits. Maximum frequency is dependent on the SKU and number of active cores. No special hardware support is necessary for Intel Turbo Boost Technology. BIOS and the operating system can enable or disable Intel Turbo Boost Technology.

Note: Intel Turbo Boost Technology may not be available on all SKUs. Refer to the processor specification update for details.

§§

4 Power Management

This chapter provides information on the following power management topics:

- ACPI States
- Processor Core
- IMC
- PCI Express*

4.1 ACPI States Supported

The ACPI states supported by the processor are described in this section.

4.1.1 System States

State	Description	
G0/S0	Full On	
G1	Suspend-to-RAM (STR).	
G1/S4	Suspend-to-Disk (STD). All power lost (except wakeup on PCH).	
G2/S5	Soft off. All power lost (except wakeup on PCH). Total reboot.	
G3	Mechanical off. All power removed from system.	

4.1.2 Processor Core/Package Idle States

Table 4-1. Processor Core/Package State Support

State	Description	
CO	Active mode, processor executing code.	
C1	AutoHALT state.	
C1E	AutoHALT state with lowest frequency and voltage operating point.	
СЗ	Execution cores in C3 flush their L1 instruction cache, L1 data cache, and L cache to the L3 shared cache. Clocks are shut off to the core.	
C6	Execution cores in this state save their architectural state before removing core voltage.	

4.1.3 Integrated Memory Controller States

State	Description	
Power up	CKE asserted. Active mode.	
Pre-charge Power down	CKE de-asserted (not self-refresh) with all banks closed.	
Active Power down	CKE de-asserted (not self-refresh) with minimum one bank active.	
Self-Refresh	h CKE de-asserted using device self-refresh.	

4.1.4 PCI Express* Link States

State	Description	
LO	Full on – Active transfer state.	
LOs	First Active Power Management low power state – Low exit latency.	
L1	Lowest Active Power Management - Longer exit latency.	
L3	Lowest power state (power-off) – Longest exit latency.	

4.1.5 Interface State Combinations

Table 4-2. G, S, and C State Combinations

Global (G) State	Sleep (S) State	Processor Core (C) State	Processor State	System Clocks	Description
G0	S0	CO	Full On	On	Full On
GO	S0	C1/C1E	Auto-Halt	On	Auto-Halt
G0	S0	C3	Deep Sleep	On	Deep Sleep
GO	SO	C6	Deep Power Down	On	Deep Power Down
G1	—	Power off	Power off	Off, except RTC	Suspend to RAM
G1	S4	Power off	Power off	Off, except RTC	Suspend to Disk
G2	S5	Power off	Power off	Off, except RTC	Soft Off
G3	NA	Power off	Power off	Power off	Hard off

4.2 Processor Core Power Management

While executing code, Enhanced Intel SpeedStep Technology optimizes the processor's frequency and core voltage based on workload. Each frequency and voltage operating point is defined by ACPI as a P-state. When the processor is not executing code, it is idle. A low-power idle state is defined by ACPI as a C-state. In general, lower power C-states have longer entry and exit latencies.

4.2.1 Enhanced Intel[®] SpeedStep[®] Technology

The following are the key features of Enhanced Intel SpeedStep Technology:

- Multiple frequency and voltage points for optimal performance and power efficiency. These operating points are known as P-states.
- Frequency selection is software controlled by writing to processor MSRs. The voltage is optimized based on the selected frequency and the number of active processor cores.
 - If the target frequency is higher than the current frequency, V_{CC} is ramped up in steps to an optimized voltage. This voltage is signaled by the VID[7:0] pins to the voltage regulator. Once the voltage is established, the PLL locks on to the target frequency.
 - If the target frequency is lower than the current frequency, the PLL locks to the target frequency, then transitions to a lower voltage by signaling the target voltage on the VID[7:0] pins.
 - All active processor cores share the same frequency and voltage. In a multicore processor, the highest frequency P-state requested amongst all active cores is selected.
 - Software-requested transitions are accepted at any time. If a previous transition is in progress, the new transition is deferred until the previous transition is completed.
- The processor controls voltage ramp rates internally to ensure glitch-free transitions.
- Because there is low transition latency between P-states, a significant number of transitions per second are possible.

4.2.2 Low-Power Idle States

When the processor is idle, low-power idle states (C-states) are used to save power. More power savings actions are taken for numerically higher C-states. However, higher C-states have longer exit and entry latencies. Resolution of C-states occur at the thread, processor core, and processor package level. Thread level C-states are available if Intel Hyper-Threading Technology is enabled.

Figure 4-1. Idle Power Management Breakdown of the Processor Cores

Entry and exit of the C-States at the thread and core level are shown in Figure 4-2.

Figure 4-2. Thread and Core C-State Entry and Exit

While individual threads can request low power C-states, power saving actions only take place once the core C-state is resolved. Core C-states are automatically resolved by the processor. For thread and core C-states, a transition to and from CO is required before entering any other C-state.

Processor Core		Thread 1			
C-S	C-State C0 C1 C3 C6		C6		
	СО	CO	CO	CO	CO
Thread 0	C1	CO	C1 ¹	C1 ¹	C1 ¹
Thread O	С3	CO	C1 ¹	C3	C3
	C6	CO	C1 ¹	C3	C6

Table 4-3. Coordination of Thread Power States at the Core Level

Note:

1. If enabled, the core C-state will be C1E if all active cores have also resolved to a core C1 state or higher.

4.2.3 Requesting Low-Power Idle States

The primary software interfaces for requesting low-power idle states are through the MWAIT instruction with sub-state hints and the HLT instruction (for C1 and C1E). However, software may make C-state requests using the legacy method of I/O reads from the ACPI-defined processor clock control registers, referred to as P_LVLx. This method of requesting C-states provides legacy support for operating systems that initiate C-state transitions using I/O reads.

For legacy operating systems, P_LVLx I/O reads are converted within the processor to the equivalent MWAIT C-state request. Therefore, P_LVLx reads do not directly result in I/O reads to the system. The feature, known as I/O MWAIT redirection, must be enabled in the BIOS.

Note: The P_LVLx I/O Monitor address needs to be set up before using the P_LVLx I/O read interface. Each P-LVLx is mapped to the supported MWAIT(Cx) instruction as follows:

Table 4-4. P_LVLx to MWAIT Conversion

P_LVLx	MWAIT(Cx)	Notes
P_LVL2	MWAIT(C3)	
P_LVL3	MWAIT(C6)	C6. No sub-states allowed

The BIOS can write to the C-state range field of the PMG_IO_CAPTURE MSR to restrict the range of I/O addresses that are trapped and emulate MWAIT like functionality. Any P_LVLx reads outside of this range does not cause an I/O redirection to MWAIT(Cx) like request. They fall through like a normal I/O instruction.

Note: When P_LVLx I/O instructions are used, MWAIT substates cannot be defined. The MWAIT substate is always zero if I/O MWAIT redirection is used. By default, P_LVLx I/O redirections enable the MWAIT 'break on EFLAGS.IF' feature that triggers a wakeup on an interrupt, even if interrupts are masked by EFLAGS.IF.

4.2.4 Core C-states

The following are general rules for all core C-states, unless specified otherwise:

- A core C-State is determined by the lowest numerical thread state (such that, Thread 0 requests C1E while thread1 requests C3, resulting in a core C1E state). See Table 4-3.
- A core transitions to C0 state when:
 - an interrupt occurs.
 - there is an access to the monitored address if the state was entered using an MWAIT instruction.
- For core C1/C1E, and core C3, an interrupt directed toward a single thread wakes only that thread. However, since both threads are no longer at the same core C-state, the core resolves to C0.
- For core C6, an interrupt coming into either thread wakes both threads into C0 state.
- Any interrupt coming into the processor package may wake any core.

4.2.4.1 Core CO State

The normal operating state of a core where code is being executed.

4.2.4.2 Core C1/C1E State

C1/C1E is a low power state entered when all threads within a core execute a HLT or MWAIT(C1/C1E) instruction.

A System Management Interrupt (SMI) handler returns execution to either Normal state or the C1/C1E state. See the Intel[®] 64 and IA-32 Architecture Software Developer's Manual, Volume 3A/3B: System Programmer's Guide for more information.

While a core is in C1/C1E state, it processes bus snoops and snoops from other threads. For more information on C1E, see Section 4.2.5.2.

4.2.4.3 Core C3 State

Individual threads of a core can enter the C3 state by initiating a P_LVL2 I/O read to the P_BLK or an MWAIT(C3) instruction. A core in C3 state flushes the contents of its L1 instruction cache, L1 data cache, and L2 cache to the shared L3 cache, while maintaining its architectural state. All core clocks are stopped at this point. Because the core's caches are flushed, the processor does not wake any core that is in the C3 state when either a snoop is detected or when another core accesses cacheable memory.

4.2.4.4 Core C6 State

Individual threads of a core can enter the C6 state by initiating a P_LVL3 I/O read or an MWAIT(C6) instruction. Before entering core C6, the core will save its architectural state to a dedicated SRAM. Once complete, a core will have its voltage reduced to zero volts. During exit, the core is powered on and its architectural state is restored.

4.2.4.5 C-State Auto-Demotion

In general, deeper C-states, such as C6, have long latencies and have higher energy entry/exit costs. The resulting performance and energy penalties become significant when the entry/exit frequency of a deeper C-state is high.

Therefore, incorrect or inefficient usage of deeper C-states may have a negative impact on power consumption. To increase residency and improve power consumption in deeper C-states, the processor supports C-state auto-demotion.

There are two C-State auto-demotion options:

- C6 to C3
- C6/C3 To C1

The decision to demote a core from C6 to C3 or C3/C6 to C1 is based on each core's residency history. Requests to deeper C-states are demoted to shallower C-states when the original request doesn't make sense from a performance or energy perspective.

This feature is disabled by default. BIOS must enable it in the PMG_CST_CONFIG_CONTROL register. The auto-demotion policy is also configured by this register.

4.2.5 Package C-States

The processor supports C0, C1/C1E, C3, and C6 power states. The following is a summary of the general rules for package C-state entry. These apply to all package C-states unless specified otherwise:

- A package C-state request is determined by the lowest numerical core C-state amongst all cores.
- A package C-state is automatically resolved by the processor depending on the core idle power states and the status of the platform components.
 - Each core can be at a lower idle power state than the package if the platform does not grant the processor permission to enter a requested package C-state.
 - The platform may allow additional power savings to be realized in the processor. The processor will put the DRAM into self-refresh in the package C3 and C6 states.
- For package C-states, the processor is not required to enter C0 before entering any other C-state.

The processor exits a package C-state when a break event is detected. If DRAM was allowed to go into self-refresh in package C3 or C6 state, it will be taken out of self-refresh. Depending on the type of break event, the processor does the following:

- If a core break event is received, the target core is activated and the break event message is forwarded to the target core.
 - If the break event is not masked, the target core enters the core C0 state and the processor enters package C0.
 - If the break event is masked, the processor attempts to re-enter its previous package state.
- If the break event was due to a memory access or snoop request.
 - But the platform did not request to keep the processor in a higher package Cstate, the package returns to its previous C-state.
 - And the platform requests a higher power C-state, the memory access or snoop request is serviced and the package remains in the higher power C-state.

Table 4-5 shows an example package C-state resolution for a dual-core processor. Figure 4-3 summarizes package C-state transitions.

Table 4-5. Coordination of Core Power States at the Package Level

Package C-State		Core 1				
		CO	C1 ¹	C3	C6	
	CO	CO	CO	CO	CO	
Core 0	C1 ¹	CO	C1 ¹	C1 ¹	C1 ¹	
coreo	C3	CO	C1 ¹	C3	C3	
	C6	CO	C1 ¹	C3	C6	

Note:

1. If enabled, the package C-state will be C1E if all actives cores have resolved a core C1 state or higher.

Figure 4-3. Package C-State Entry and Exit

4.2.5.1 Package CO

The normal operating state for the processor. The processor remains in the normal state when at least one of its cores is in the C0 or C1 state or when the platform has not granted permission to the processor to go into a low power state. Individual cores may be in lower power idle states while the package is in C0.

4.2.5.2 Package C1/C1E

No additional power reduction actions are taken in the package C1 state. However, if the C1E sub-state is enabled, the processor automatically transitions to the lowest supported core clock frequency, followed by a reduction in voltage.

The package enters the C1 low power state when:

- At least one core is in the C1 state.
- The other cores are in a C1 or lower power state.

The package enters the C1E state when:

- All cores have directly requested C1E using MWAIT(C1) with a C1E sub-state hint.
- All cores are in a power state lower that C1/C1E but the package low power state is limited to C1/C1E using the PMG_CST_CONFIG_CONTROL MSR.
- All cores have requested C1 using HLT or MWAIT(C1) and C1E auto-promotion is enabled in IA32_MISC_ENABLES.

No notification to the system occurs upon entry to C1/C1E.

4.2.5.3 Package C3 State

A processor enters the package C3 low power state when:

- At least one core is in the C3 state.
- The other cores are in a C3 or lower power state, and the processor has been granted permission by the platform.
- The processor has requested the C6 state, but the platform only allowed C3.

In package C3-state, the L3 shared cache is snoopable.

4.2.5.4 Package C6 State

A processor enters the package C6 low power state when:

- At least one core is in the C6 state.
- The other cores are in a C6 state, and the processor has been granted permission by the platform.

In package C6 state, all cores save their architectural state and have their core voltages reduced. The L3 shared cache is still powered and snoopable in this state.

4.3 IMC Power Management

The main memory is power managed during normal operation and in low power ACPI Cx states.

4.3.1 Disabling Unused System Memory Outputs

Any system memory (SM) interface signal that goes to a memory module connector in which it is not connected to any actual memory devices (such as, DIMM connector is unpopulated, or is single-sided) is tristated. The benefits of disabling unused SM signals are:

- Reduced power consumption.
- Reduced possible overshoot/undershoot signal quality issues seen by the processor I/O buffer receivers caused by reflections from potentially un-terminated transmission lines.

When a given rank is not populated, the corresponding chip select and SCKE signals are not driven.

At reset, all rows must be assumed to be populated, until it can be proven that they are not populated. This is due to the fact that when CKE is tristated with a DIMM present, the DIMM is not ensured to maintain data integrity.

4.3.2 DRAM Power Management and Initialization

The processor implements extensive support for power management on the SDRAM interface. There are four SDRAM operations associated with the Clock Enable (CKE) signals, which the SDRAM controller supports. The processor drives four CKE pins to perform these operations.

4.3.2.1 Initialization Role of CKE

During power-up, CKE is the only input to the SDRAM that has its level recognized (other than the DDR3 reset pin) once power is applied. It must be driven LOW by the DDR controller to make sure the SDRAM components float DQ and DQS during power-up. CKE signals remain LOW (while any reset is active) until the BIOS writes to a configuration register. Using this method, CKE is ensured to remain inactive for much longer than the specified 200 micro-seconds after power and clocks to SDRAM devices are stable.

4.3.2.2 Conditional Self-Refresh

The processor conditionally places memory into self-refresh in the C3 and C6 low power states.

When entering the Suspend-to-RAM (STR) state, the processor core flushes pending cycles and then enters all SDRAM ranks into self refresh. In STR, the CKE signals remain LOW so the SDRAM devices perform self refresh.

The target behavior is to enter self-refresh for the package C3 and C6 states as long as there are no memory requests to service. The target usage is shown in Table 4-6.

Table 4-6. Targeted Memory State Conditions

Mode	Memory State with External Graphics
C0, C1, C1E	Dynamic memory rank power down based on idle conditions.
C3, C6	Dynamic memory rank power down based on idle conditions If there are no memory requests, then enter self-refresh. Otherwise, use dynamic memory rank power down based on idle conditions.
S4	Memory power down (contents lost)

4.3.2.3 Dynamic Power Down Operation

Dynamic power-down of memory is employed during normal operation. Based on idle conditions, a given memory rank may be powered down. The IMC implements aggressive CKE control to dynamically put the DRAM devices in a power down state. The processor core controller can be configured to put the devices in *active power down* (CKE de-assertion with open pages) or *precharge power down* (CKE de-assertion with all pages closed). Precharge power down provides greater power savings but has a bigger performance impact, since all pages will first be closed before putting the devices in power down mode.

If dynamic power-down is enabled, all ranks are powered up before doing a refresh cycle and all ranks are powered down at the end of refresh.

4.3.2.4 DRAM I/O Power Management

Unused signals should be disabled to save power and reduce electromagnetic interference. This includes all signals associated with an unused memory channel. Clocks can be controlled on a per DIMM basis. Exceptions are made for per DIMM control signals, such as CS#, CKE, and ODT for unpopulated DIMM slots.

The I/O buffer for an unused signal should be tristated (output driver disabled), the input receiver (differential sense-amp) should be disabled, and any DLL circuitry related ONLY to unused signals should be disabled. The input path must be gated to prevent spurious results due to noise on the unused signals (typically handled automatically when input receiver is disabled).

4.4 PCI Express* Power Management

- Active power management support using LOs, and L1 states.
- All inputs and outputs disabled in L3 Ready state.

Power Management

5 Thermal Management

For thermal specifications and design guidelines, refer to the appropriate Thermal and Mechanical Specifications and Design Guidelines (see Section 1.7).

Thermal Management

6 Signal Description

This chapter describes the processor signals. They are arranged in functional groups according to their associated interface or category. The following notations are used to describe the signal type.

Notations	Signal Type
I	Input Pin
0	Output Pin
1/0	Bi-directional Input/Output Pin

The signal description also includes the type of buffer used for the particular signal.

Table 6-1.Signal Description Buffer Types

Signal	Description
PCI Express*	PCI Express* interface signals. These signals are compatible with the PCI Express 2.0 Signaling Environment AC Specifications and are AC Coupled. The buffers are not 3.3 V tolerant. Refer to the PCI Express Specification.
FDI	Intel Flexible Display Interface signals. These signals are compatible with PCI Express 2.0 Signaling Environment AC Specifications, but are DC coupled. The buffers are not 3.3 V tolerant.
DMI	Direct Media Interface signals. These signals are compatible with PCI Express 2.0 Signaling Environment AC Specifications, but are DC coupled. The buffers are not 3.3 V tolerant.
CMOS	CMOS buffers. 1.1 V tolerant
DDR3	DDR3 buffers: 1.5 V tolerant
GTL	Gunning Transceiver Logic signaling technology
ТАР	Test Access Port signal
Analog	Analog reference or output. May be used as a threshold voltage or for buffer compensation.
Ref	Voltage reference signal
Asynch	This signal is asynchronous and has no timing relationship with any reference clock.

6.1 System Memory Interface

Table 6-2.Memory Channel A

Signal Name	Description	Direction	Туре
SA_BS[2:0]	Bank Select: These signals define which banks are selected within each SDRAM rank.	0	DDR3
SA_CAS#	CAS Control Signal: This signal is used with SA_RAS# and SA_WE# (along with SA_CS#) to define the SDRAM Commands.	0	DDR3
SA_CK#[1:0]	SDRAM Inverted Differential Clock: Channel A SDRAM Differential clock signal-pair complement.	0	DDR3
SA_CK#[3:2]	SDRAM Inverted Differential Clock: Channel A SDRAM Differential clock signal-pair complement.	0	DDR3
SA_CK[1:0]	SDRAM Differential Clock: Channel A SDRAM Differential clock signal pair. The crossing of the positive edge of SA_CKx and the negative edge of its complement SA_CKx# are used to sample the command and control signals on the SDRAM.	Ο	DDR3
SA_CK[3:2]	SDRAM Differential Clock: Channel A SDRAM Differential clock signal pair. The crossing of the positive edge of SA_CKx and the negative edge of its complement SA_CKx# are used to sample the command and control signals on the SDRAM.	0	DDR3
SA_CKE[3:0]	 Clock Enable: (1 per rank). These signals are used to: Initialize the SDRAMs during power-up Power-down SDRAM ranks Place all SDRAM ranks into and out of self-refresh during STR 	0	DDR3
SA_CS#[3:0]	Chip Select: (1 per rank) These signals are used to select particular SDRAM components during the active state. There is one Chip Select for each SDRAM rank.	0	DDR3
SA_CS#[7:4]	These signals are only used for processors and platforms that have Registered DIMM support. These signals are used to select particular SDRAM components during the active state and SA_CS#[7:6] are used as the on die termination for the first DIMM.	0	DDR3
SA_DM[7:0]	Data Mask: These signals are used to mask individual bytes of data in the case of a partial write, and to interrupt burst writes. When activated during writes, the corresponding data groups in the SDRAM are masked. There is one SA_DM[7:0] for every data byte lane. Note: These signals are not used by the Intel Xeon processor 3400 series. They are connected to V _{SS} on the package.		
SA_DQ[63:0]	Data Bus: Channel A data signal interface to the SDRAM data bus.	1/0	DDR3
SA_DQS[8:0] SA_DQS#[8:0]	Data Strobes: SA_DQS[8:0] and its complement signal group make up a differential strobe pair. The data is captured at the crossing point of SA_DQS[8:0] and its SA_DQS#[8:0] during read and write transactions.	1/0	DDR3
SA_ECC_CB[7:0]	Data Lines for ECC Check Byte.	1/0	DDR3
SA_MA[15:0]	Memory Address: These signals are used to provide the multiplexed row and column address to the SDRAM.	0	DDR3
SA_ODT[3:0]	On Die Termination: Active Termination Control	0	DDR3
SA_RAS#	RAS Control Signal: This signal is used with SA_CAS# and SA_WE# (along with SA_CS#) to define the SRAM Commands.	0	DDR3
SA_WE#	Write Enable Control Signal: This signal is used with SA_RAS# and SA_CAS# (along with SA_CS#) to define the SDRAM Commands.	0	DDR3

BCLK_ITP BCLK_ITP#	Buffered differential bus clock pair to ITP	0	Diff Clk	
PEG_CLK PEG_CLK#	Differential PCI Express / DMI Clock In: These pins receive a 100-MHz Serial Reference clock. This clock is used to generate the clocks necessary for the support of PCI Express. This also is the reference clock for Intel [®] Flexible Display Interface.	I	Diff Clk	

The signals noted below as not being used are included for reference to define all LGA

6.7 Intel[®] Flexible Display Interface Signals

Note:

1156 land locations. These signals will be used by future processors that are compatible with LGA 1156 platforms. Table 6-9. Intel[®] Flexible Display Interface

Signal Name	Description	Direction	Туре
FDI_FSYNC[0]	Intel [®] Flexible Display Interface Frame Sync—Pipe A. Note: This signal is not used by the processor. It is connected to V_{SS} on the package.		
FDI_FSYNC[1]	Intel [®] Flexible Display Interface Frame Sync—Pipe B. Note: This signal is not used by the processor. It is connected to V _{SS} on the package.		
FDI_INT	Intel [®] Flexible Display Interface Hot Plug Interrupt. Note: This signal is not used by the processor. It is connected to V _{SS} on the package.		
FDI_LSYNC[0]	$\label{eq:states} \begin{array}{l} \mbox{Intel}^{\ensuremath{\mathbb{R}}} \ \mbox{Flexible Display Interface Line Sync-Pipe A.} \\ \mbox{Note: This signal is not used by the processor. It is connected to V_{SS} on the package.} \end{array}$		
FDI_LSYNC[1]	Intel [®] Flexible Display Interface Line Sync—Pipe B. Note: This signal is not used by the processor. It is connected to V _{SS} on the package.		
FDI_TX[3:0] FDI_TX#[3:0]	Intel [®] Flexible Display Interface Transmit Differential Pair—Pipe A Note: These signals are not used by the processor. They are connected to V _{SS} on the package.		
FDI_TX[7:4] FDI_TX#[7:4]	Intel [®] Flexible Display Interface Transmit Differential Pair—Pipe B. Note: These signals are not used by the processor. They are connected to V _{SS} on the package.		

6.8 JTAG/ITP Signals

Table 6-10. JTAG/ITP

Signal Name	Description	Direction	Туре
BPM#[7:0]	Breakpoint and Performance Monitor Signals: Outputs from the processor that indicate the status of breakpoints and programmable counters used for monitoring processor performance.	1/0	GTL
DBR#	DBR# is used only in systems where no debug port is implemented on the system board. DBR# is used by a debug port interposer so that an in-target probe can drive system reset.	0	
PRDY#	PRDY# is a processor output used by debug tools to determine processor debug readiness.	0	Asynch GTL
PREQ#	PREQ# is used by debug tools to request debug operation of the processor.	I	Asynch GTL
тск	TCK (Test Clock) provides the clock input for the processor Test Bus (also known as the Test Access Port).	I	TAP
TDI	TDI (Test Data In) transfers serial test data into the processor. TDI provides the serial input needed for JTAG specification support.	I	ТАР
TDI_M	TDI_M (Test Data In) transfers serial test data into the processor. TDI_M provides the serial input needed for JTAG specification support.	I	ТАР
TDO	TDO (Test Data Out) transfers serial test data out of the processor. TDO provides the serial output needed for JTAG specification support.	0	ТАР
TDO_M	TDO_M (Test Data Out) transfers serial test data out of the processor. TDO_M provides the serial output needed for JTAG specification support.	0	ТАР
TMS	TMS (Test Mode Select) is a JTAG specification support signal used by debug tools.	I	TAP
TRST#	TRST# (Test Reset) resets the Test Access Port (TAP) logic. TRST# must be driven low during power on Reset.	I	TAP

6.9 Error and Thermal Protection

Table 6-11. Error and Thermal Protection

Signal Name	Description	Direction	Туре	
CATERR#	Catastrophic Error: This signal indicates that the system has experienced a catastrophic error and cannot continue to operate. The processor will set this for non-recoverable machine check errors or other unrecoverable internal errors. Since this is an I/O pin, external agents are allowed to assert this pin that will cause the processor to take a machine check exception. CATERR# is used for signaling the following types of errors: • Legacy MCERR: CATERR# is asserted for 16 BCLKs. • Legacy IERR: CATERR# remains asserted until warm or cold reset.	1/0	GTL	
PECI	PECI (Platform Environment Control Interface) is the serial sideband interface to the processor and is used primarily for thermal, power, and error management.	1/0	Asynch	
PROCHOT#	PROCHOT# goes active when the processor temperature monitoring sensor(s) detects that the processor has reached its maximum safe operating temperature. This indicates that the processor Thermal Control Circuit has been activated, if enabled. This signal can also be driven to the processor to activate the Thermal Control Circuit. This signal does not have on-die termination and must be terminated on the system board.	1/0	Asynch GTL	
PSI#	Processor Power Status Indicator: This signal is asserted when maximum possible processor core current consumption is less than 15 A. Assertion of this signal is an indication that the VR controller does not currently need to be able to provide I_{CC} above 15 A, and the VR controller can use this information to move to more efficient operating point. This signal will de-assert at least 3.3 µs before the current consumption will exceed 15 A. The minimum PSI# assertion and de-assertion time is 1 BCLK.	0	Asynch CMOS	
THERMTRIP#	Thermal Trip: The processor protects itself from catastrophic overheating by use of an internal thermal sensor. This sensor is set well above the normal operating temperature to ensure that there are no false trips. The processor will stop all execution when the junction temperature exceeds approximately 125 °C. This is signaled to the system by the THERMTRIP# pin.	Ο	Asynch GTL	

6.10 Power Sequencing

Table 6-12. Power Sequencing

Signal Name	Description	Direction	Туре
SKTOCC#	SKTOCC# (Socket Occupied): This signal will be pulled to ground on the processor package. There is no connection to the processor silicon for this signal. System board designers may use this signal to determine if the processor is present.	0	
SM_DRAMPWROK	SM_DRAMPWROK processor input: This signal connects to PCH DRAMPWROK.	I	Asynch CMOS
TAPPWRGOOD	Power good for ITP. Indicates to the ITP when the TAP can be accessed.	0	Asynch CMOS
VCCPWRGOOD_0 VCCPWRGOOD_1	VCCPWRGOOD_0 and VCCPWRGOOD_1 (Power Good) Processor Input: The processor requires these signals to be a clean indication that V_{CC} , V_{CCPLL} , V_{TT} , V_{AXG} supplies are stable and within their specifications and that BCLK is stable and has been running for a minimum number of cycles. These signals must then transition monotonically to a high state. These signals can be driven inactive at any time, but BCLK and power must again be stable before a subsequent rising edge of VCCPWRGOOD_0 and VCCPWRGOOD_1. These signals should be tied together and connected to the CPUPWRGD output signal of the PCH.	I	Asynch CMOS
VTTPWRGOOD	PWRGOOD The processor requires this input signal to be a clean indication that the V _{TT} power supply is stable and within specifications. 'Clean' implies that the signal will remain low (capable of sinking leakage current), without glitches, from the time that the power supplies are turned on until they come within specification. The signal must then transition monotonically to a high state. Note that it is not valid for VTTPWRGOOD to be de-asserted while VCCPWRGOOD_0 and VCCPWRGOOD_1 are asserted.		Asynch CMOS

6.11 Processor Core Power Signals

Table 6-13. Processor Core Power Signals (Sheet 1 of 2)

Signal Name	Description	Direction	Туре	
ISENSE	Current sense from VRD11.1 Compliant Regulator to the processor core.	I	Analog	
VCC	Processor core power supply. The voltage supplied to these pins is determined by the VID pins.		PWR	
VCC_NCTF	VCC/Non-Critical to Function: Pin for package mechanical reliability.		PWR	
VCC_SENSE	VCC_SENSE and VSS_SENSE provide an isolated, low impedance connection to the processor core voltage and ground. They can be used to sense or measure voltage near the silicon.		Analog	

Table 6-13. Processor Core Power Signals (Sheet 2 of 2)

Signal Name	Description	Direction	Туре
VID[7:6] VID[5:3]/CSC[2:0] VID[2:0]/MSID[2:0]	VID[7:0] (Voltage ID) are used to support automatic selection of power supply voltages (V _{CC}). Refer to the Voltage Regulator-Down (VRD) 11.1 Design Guidelines for more information. The voltage supply for these signals must be valid before the VR can supply V _{CC} to the processor. Conversely, the VR output must be disabled until the voltage supply for the VID signals become valid. The VR must supply the voltage that is requested by the signals, or disable itself. VID7 and VID6 should be tied separately to V _{SS} using a 1 kΩ resistor (This value is latched on the rising edge of VTTPWRGOOD). CSC[2:0]—Current Sense Configuration bits, for ISENSE gain setting. See Voltage Regulator-Down (VRD) 11.1 Design Guidelines for gain setting information. This value is latched on the rising edge of VTTPWRGOOD. MSID[2:0] (Market Segment Identification) are used to indicate the maximum platform capability to the processor. A processor will only boot if the MSID[2:0] pins are strapped to the appropriate setting (or higher) on the platform (see Table 7-3 for MSID encodings). MSID is used to help protect the platform by preventing	1/0	CMOS
VSS_SENSE	a higher power processor from booting in a platform designed for lower power processors. MSID[2:0] are latched on the rising edge of VTTPWRGOOD. VCC_SENSE and VSS_SENSE provide an isolated, low impedance connection to the processor core voltage and ground. They can be used to sense or measure voltage near the silicon.		Analog
VSS_SENSE_VTT	VTT_SENSE and VSS_SENSE_VTT provide an isolated, low impedance connection to the processor V_{TT} voltage and ground. They can be used to sense or measure voltage near the silicon.		Analog
VTT	Processor power for the memory controller, shared cache and I/O (1.1 V).		PWR
VTT_SELECT	The VTT_SELECT signal is used to select the correct V_{TT} voltage level for the processor. The processor will be configured to drive a low voltage level for VTT_SELECT.	0	CMOS
VTT_SENSE	VTT_SENSE and VSS_SENSE_VTT provide an isolated, low impedance connection to the processor V_{TT} voltage and ground. They can be used to sense or measure voltage near the silicon.		Analog

6.12 Graphics and Memory Core Power Signals

Note: The signals noted below as not being used are included for reference to define all LGA 1156 land locations. These signals will be used by future processors that are compatible with LGA 1156 platforms.

Table 6-14. Graphics and Memory Power Signals

Signal Name	Description	Direction	Туре
GFX_DPRSLPVR	Integrated graphics output signal to a VRD11.1 compliant VR. When asserted this signal indicates that the integrated graphics is in render suspend mode. This signal is also used to control render suspend state exit slew rate. Note: This signal is not used by the processor. It is		
	connected to V _{SS} on the package.		
GFX_IMON	Current Sense from an VRD11.1 compliant VR to the integrated graphics. Note: This signal is not used by the processor. It is connected to V _{SS} on the package.		
GFX_VID[6:0]	$\begin{array}{l} {\sf GFX_VID[6:0]} \mbox{ (Voltage ID) pins are used to support automatic selection of nominal voltages (V_{AXG}). These are CMOS signals that are driven by the processor. The VID code output by VID[6:0] and associated voltages are given in Chapter 7. \\ {\sf Note:} These signals are not used by the processor. They are connected to V_{TT} on the package. \end{array}$		
GFX_VR_EN	Integrated graphics output signal to integrated graphics VR. This signal is used as an on/off control to enable/disable the integrated graphics VR. Note: This signal is not used by the processor. It is connected to V _{SS} on the package.		
VAXG	Graphics core power supply. Note: These signals are not used by the processor. They are no connect on the package.		
VAXG_SENSE	VAXG_SENSE and VSSAXG_SENSE provide an isolated, low impedance connection to the VAXG voltage and ground. They can be used to sense or measure voltage near the silicon. Note: This signal is not used by the processor. It is a no connect on the package.		
VCCPLL	VCCPLL provides isolated power for internal processor PLLs.		PWR
VDDQ	Processor I/O supply voltage for DDR3.		PWR
VSSAXG_SENSE	VAXG_SENSE and VSSAXG_SENSE provide an isolated, low impedance connection to the VAXG voltage and ground. They can be used to sense or measure voltage near the silicon. Note: This signal is not used by the processor. It is connected to V _{SS} on the package.		

6.13 Ground and NCTF

Table 6-15. Ground and NCTF

Signal Name	Description	Direction	Туре
VSS	VSS are the ground pins for the processor and should be connected to the system ground plane.		GND
CGC_TP_NCTF	Corner Ground Connection: This land may be used to test for connection to ground. A test point may be placed on the board for this land. This land is considered Non- Critical to Function.		

6.14 Processor Internal Pull Up/Pull Down

Signal Name	Pull Up/Pull Down	Rail	Value
SM_DRAMPWROK	Pull Down	VSS	10–20 kΩ
VCCPWRGOOD_0 VCCPWRGOOD_1	Pull Down	VSS	10–20 kΩ
VTTPWRGOOD	Pull Down	VSS	10–20 kΩ
BPM#[7:0]	Pull Up	VTT	44–55 Ω
тск	Pull Up	VTT	44–55 Ω
TDI	Pull Up	VTT	44–55 Ω
TMS	Pull Up	VTT	44–55 Ω
TRST#	Pull Up	VTT	1–5 kΩ
TDI_M	Pull Up	VTT	44–55 Ω
PREQ#	Pull Up	VTT	44–55 Ω
CFG[17:0]	Pull Up	VTT	5–14 kΩ

Table 6-16. Processor Internal Pull Up/Pull Down

§§

7 Electrical Specifications

7.1 Power and Ground Lands

The processor has VCC, VTT, VDDQ, VCCPLL, VAXG, and VSS (ground) inputs for onchip power distribution. All power lands must be connected to their respective processor power planes, while all VSS lands must be connected to the system ground plane. Use of multiple power and ground planes is recommended to reduce I*R drop. The VCC lands must be supplied with the voltage determined by the processor **V**oltage **ID**entification (VID) signals. Table 7-1 specifies the voltage level for the various VIDs.

7.2 Decoupling Guidelines

Due to its large number of transistors and high internal clock speeds, the processor is capable of generating large current swings between low- and full-power states. This may cause voltages on power planes to sag below their minimum values, if bulk decoupling is not adequate. Larger bulk storage (C_{BULK}), such as electrolytic capacitors, supply current during longer lasting changes in current demand (for example, coming out of an idle condition). Similarly, capacitors act as a storage well for current when entering an idle condition from a running condition. To keep voltages within specification, output decoupling must be properly designed.

Caution: Design the board to ensure that the voltage provided to the processor remains within the specifications listed in Table 7-5. Failure to do so can result in timing violations or reduced lifetime of the processor. For further information and design guidelines, refer to the *Voltage Regulator Down (VRD) 11.1 Design Guidelines.*

7.2.1 Voltage Rail Decoupling

The voltage regulator solution needs to provide:

- bulk capacitance with low effective series resistance (ESR).
- a low interconnect resistance from the regulator to the socket.
- bulk decoupling to compensate for large current swings generated during poweron, or low-power idle state entry/exit.

The power delivery solution must ensure that the voltage and current specifications are met, as defined in Table 7-5.

7.3 Processor Clocking (BCLK[0], BCLK#[0])

The processor uses a differential clock to generate the processor core(s) operating frequency, memory controller frequency, and other internal clocks. The processor core frequency is determined by multiplying the processor core ratio by 133 MHz. Clock multiplying within the processor is provided by an internal phase locked loop (PLL) that requires a constant frequency input, with exceptions for Spread Spectrum Clocking (SSC).

The processor maximum core frequency is configured during power-on reset by using its manufacturing default value. This value is the highest core multiplier at which the processor can operate. If lower maximum speeds are desired, the appropriate ratio can be configured using the FLEX_RATIO MSR.

7.3.1 PLL Power Supply

An on-die PLL filter solution is implemented on the processor. Refer to Table 7-6 for DC specifications.

7.4 V_{CC} Voltage Identification (VID)

The VID specification for the processor is defined by the *Voltage Regulator Down (VRD) 11.1 Design Guidelines*. The processor uses eight voltage identification signals, VID[7:0], to support automatic selection of voltages. Table 7-1 specifies the voltage level corresponding to the state of VID[7:0]. A '1' in this table refers to a high voltage level and a '0' refers to a low voltage level. If the processor socket is empty (VID[7:0] = 1111111), or the voltage regulation circuit cannot supply the voltage Regulator Down (*VRD*) *11.1 Design Guidelines* for further details. VID signals are CMOS push/pull drivers. Refer to Table 7-9 for the DC specifications for these signals. The VID codes will change due to temperature and/or current load changes to minimize the power of the part. A voltage range is provided in Table 7-5. The specifications are set so that one voltage regulator can operate with all supported frequencies.

Individual processor VID values may be set during manufacturing so that two devices at the same core frequency may have different default VID settings. This is shown in the VID range values in Table 7-5. The processor provides the ability to operate while transitioning to an adjacent VID and its associated processor core voltage (V_{CC}). This will represent a DC shift in the loadline.

Note: A low-to-high or high-to-low voltage state change will result in as many VID transitions as necessary to reach the target core voltage. Transitions above the maximum specified VID are not permitted. One VID transition occurs in 1.25 us. Table 7-1 includes VID step sizes and DC shift ranges. Minimum and maximum voltages must be maintained.

The VR used must be capable of regulating its output to the value defined by the new VID values issued. DC specifications for dynamic VID transitions are included in Table 7-5 and Table 7-7. See the *Voltage Regulator Down (VRD) 11.1 Design Guidelines* for further details.

Several of the VID signals (VID[5:3]/CSC[2:0] and VID[2:0]/MSID[2:0]) serve a dual purpose and are sampled during reset. Refer to the signal description table in Chapter 6 and Table 7-3 for further information.

Notes:

The MSID[2:0] signals are provided to indicate the maximum platform capability to the processor. 1.

- 2009A processors have thermal requirements that are equivalent to those of the Intel[®] Core™2 Duo E8000 2. processor series. Refer to the appropriate processor Thermal and Mechanical Specifications and Design Guidelines for additional information (see Section 1.7).
- 2009B processors have thermal requirements that are equivalent to those of the Intel[®] Core[™]2 Quad 3. Q9000 processor series. Refer to the appropriate processor Thermal and Mechanical Specifications and Design Guidelines for additional information (see Section 1.7).

7.5 Reserved or Unused Signals

The following are the general types of reserved (RSVD) signals and connection guidelines:

- · RSVD these signals should not be connected
- RSVD_TP these signals should be routed to a test point
- RSVD_NCTF these signals are non-critical to function and may be left unconnected

Arbitrary connection of these signals to V_{CC} , V_{TT} , V_{DDQ} , V_{CCPLL} , V_{SS} , or to any other signal (including each other) may result in component malfunction or incompatibility with future processors. See Chapter 8 for a land listing of the processor and the location of all reserved signals.

For reliable operation, always connect unused inputs or bi-directional signals to an appropriate signal level. Unused active high inputs should be connected through a resistor to ground (V_{SS}). Unused outputs may be left unconnected; however, this may interfere with some Test Access Port (TAP) functions, complicate debug probing, and prevent boundary scan testing. A resistor must be used when tying bi-directional signals to power or ground. When tying any signal to power or ground, a resistor will also allow for system testability. For details, see Table 7-9.

7.6 Signal Groups

Signals are grouped by buffer type and similar characteristics as listed in Table 7-3. The buffer type indicates which signaling technology and specifications apply to the signals. All the differential signals, and selected DDR3 and Control Sideband signals, have On-Die Termination (ODT) resistors. There are some signals that do not have ODT and need to be terminated on the board.

Table 7-3.Signal Groups (Sheet 1 of 2)¹

Signal Group	Alpha Group	Туре	Signals
System Reference Clock		·	
Differential	(a)	CMOS Input	BCLK[0], BCLK#[0], BCLK[1], BCLK#[1], PEG_CLK, PEG_CLK#

Notes:
 Refer to Chapter 6 for signal description details.
 SA and SB refer to DDR3 Channel A and DDR3 Channel B.
 These signals are only used on processors and platforms that support ECC DIMMs.
 These signals will not be actively used on the Intel Xeon processor 3400 series.

All Control Sideband Asynchronous signals are required to be asserted/de-asserted for at least eight BCLKs for the processor to recognize the proper signal state. See Section 7.9 for the DC specifications.

7.7 Test Access Port (TAP) Connection

Due to the voltage levels supported by other components in the Test Access Port (TAP) logic, Intel recommends the processor be first in the TAP chain, followed by any other components within the system. A translation buffer should be used to connect to the rest of the chain unless one of the other components is capable of accepting an input of the appropriate voltage. Two copies of each signal may be required with each driving a different voltage level.

7.8 Absolute Maximum and Minimum Ratings

Table 7-4 specifies absolute maximum and minimum ratings. At conditions outside functional operation condition limits, but within absolute maximum and minimum ratings, neither functionality nor long-term reliability can be expected. If a device is returned to conditions within functional operation limits after having been subjected to conditions outside these limits (but within the absolute maximum and minimum ratings) the device may be functional, but with its lifetime degraded depending on exposure to conditions exceeding the functional operation condition limits.

At conditions exceeding absolute maximum and minimum ratings, neither functionality nor long-term reliability can be expected. Moreover, if a device is subjected to these conditions for any length of time, it will either not function or its reliability will be severely degraded when returned to conditions within the functional operating condition limits.

Although the processor contains protective circuitry to resist damage from Electro-Static Discharge (ESD), precautions should always be taken to avoid high static voltages or electric fields.

Symbol	Parameter	Min	Мах	Unit	Notes ^{1, 2}
V_{CC}	Processor Core voltage with respect to V_{SS}	-0.3	1.40	V	6
V_{TT}	Voltage for the memory controller and Shared Cache with respect to V_{SS}	-0.3	1.40	V	
V _{DDQ}	Processor I/O supply voltage for DDR3 with respect to V _{SS}	-0.3	1.80	V	
V _{CCPLL}	Processor PLL voltage with respect to $\ensuremath{V_{SS}}$	-0.3	1.98	V	
T _{STORAGE}	Storage temperature	-40	85	°C	3, 4, 5

Table 7-4. Processor Absolute Minimum and Maximum Ratings

Notes:

 For functional operation, all processor electrical, signal quality, mechanical and thermal specifications must be satisfied.

Excessive overshoot or undershoot on any signal will likely result in permanent damage to the processor.
 Storage temperature is applicable to storage conditions only. In this scenario, the processor must not processor and processor are proported to a valtage big. Storage within these limits will not affect the processor and the processor must not processor.

receive a clock, and no lands can be connected to a voltage bias. Storage within these limits will not affect the long-term reliability of the device. For functional operation, refer to the processor case temperature specifications.

4. This rating applies to the processor and does not include any tray or packaging

5. Failure to adhere to this specification can affect the long-term reliability of the processor.

6. V_{CC} is a VID based rail.

7.9 DC Specifications

The processor DC specifications in this section are defined at the processor pads, unless noted otherwise. See Chapter 8 for the processor land listings and Chapter 6 for signal definitions. Voltage and current specifications are detailed in Table 7-5 and Table 7-6. For platform planning, refer to Table 7-7 that provides V_{CC} static and transient tolerances. This same information is presented graphically in Figure 7-1.

The DC specifications for the DDR3 signals are listed in Table 7-8 Control Sideband and Test Access Port (TAP) are listed in Table 7-9.

Table 7-5 through Table 7-6 list the DC specifications for the processor and are valid only while meeting the thermal specifications (as specified in the processor Thermal and Mechanical Specifications and Guidelines), clock frequency, and input voltages. Care should be taken to read all notes associated with each parameter.

Table 7-5. Processor Core Active and I dle Mode DC Voltage and Current Specifications

Notes:

Each processor is programmed with a maximum valid voltage identification value (VID) that is set at manufacturing and cannot be altered. Individual maximum VID values are calibrated during manufacturing such that two processors at the same frequency may have different settings within the VID range. Note that this differs from the VID employed by the processor during a power management event (Adaptive Thermal Monitor, Enhanced Intel SpeedStep Technology, or Low Power States).

2. The voltage specification requirements are measured across VCC_SENSE and VSS_SENSE lands at the socket with a 100-MHz bandwidth oscilloscope, 1.5 pF maximum probe capacitance, and 1-MΩ minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

 Refer to Table 7-7 and Figure 7-1 for the minimum, typical, and maximum V_{CC} allowed for a given current. The processor should not be subjected to any V_{CC} and I_{CC} combination wherein V_{CC} exceeds V_{CC_MAX} for a given current.

4. I_{CC_MAX} specification is based on the V_{CC_MAX} loadline. Refer to Figure 7-1 for details.

Symbol	Parameter	Min	Тур	Max	Unit	Note
V _{TT}	Voltage for the memory controller and shared cache defined at the socket motherboard VTT pinfield via.	1.045	1.10	1.155	v	1
	Voltage for the memory controller and shared cache defined across VTT_SENSE and VSS_SENSE_VTT.	1.023	1.10	1.117	v	2
V _{DDQ}	Processor I/O supply voltage for DDR3	1.425	1.5	1.575	V

Table 7-6. Processor Uncore I/O Buffer Supply DC Voltage and Current Specifications

Notes:

^{1.} V_{TT} must be provided using a separate voltage source and not be connected to V_{CC} . The voltage specification requirements are defined in the middle of the VTT pinfield at the processor socket vias on the bottom side of the baseboard. The voltage specifications are measured with a 20-MHz bandwidth oscilloscope, 1.5 pF maximum probe capacitance, and 1 M Ω minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

^{2.} V_{TT} must be provided using a separate voltage source and not be connected to V_{CC}. The voltage specification requirements are defined across VTT_SENSE and VSS_SENSE_VTT lands at the processor socket vias on the bottom side of the baseboard. The requirements across the SENSE signals account for voltage drops and impedances across the baseboard vias, socket, and processor package up to the processor Si. The voltage specifications are measured with a 20-MHz bandwidth oscilloscope, 1.5 pF maximum probe capacitance, and 1 MΩ minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

Table 7-7. V_{CC} Static and Transient Tolerance

Notes:

1.

The V_{CC_MIN} and V_{CC_MAX} loadlines represent static and transient limits. This table is intended to aid in reading discrete points on Figure 7-1. The loadlines specify voltage limits at the die measured at the VCC_SENSE and VSS_SENSE lands. Voltage regulation feedback for voltage regulator circuits must also be taken from processor VCC_SENSE and VSS_SENSE lands. Refer to the *Voltage Regulator Down (VRD) 11.1 Design Guidelines* for socket load line guidelines and VR implementation. 2. 3.

Figure 7-1. V_{CC} Static and Transient Tolerance Loadlines

Symbol	Parameter	Alpha Group	Min	Тур	Мах	Units	Notes ¹
V _{IL}	Input Low Voltage	(e,f)	_	—	0.43*V _{DDQ}	V	2,4

Table 7-8. **DDR3 Signal Group DC Specifications**

Notes:

1.

2.

tes: Unless otherwise noted, all specifications in this table apply to all processor frequencies. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value. V_{IH} and V_{OH} may experience excursions above V_{DDQ} . However, input signal drivers must comply with the signal quality specifications. This is the pull down driver resistance. R_{VTT_TERM} is the termination on the DIMM and is not controlled by the processor. COMP resistance must be provided on the system board with 1% resistors. COMP resistors are to V_{SS} . 3. 4.

5.

6. 7.

COMP3	(t)	COMP Resistance	19.8	20	20.2	Ω	5

Table 7-9. **Control Sideband and TAP Signal Group DC Specifications**

Notes:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.

Unless otherwise noted, all specifications in this table apply to all processor frequencies.
 The V_{TT} referred to in these specifications refers to instantaneous V_{TT}.
 For V_{IN} between 0 V and V_{TT}. Measured when the driver is tristated.
 V_{IH} and V_{OH} may experience excursions above V_{TT}. However, input signal drivers must comply with the signal quality specifications.
 COMP resistance must be provided on the system board with 1% resistors. COMP resistors are to V_{SS}.
 R_{SYS_TERM} is the system termination on the signal.

Table 7-10. PCI Express* DC Specifications

PEG_RBIAS	(ae)	Comp Resistance	742.5	750	757.5	Ω	4,5

Notes:

Refer to the PCI Express Base Specification for more details. 1.

 $V_{TX-AC-CM-PP}$ and $V_{TX-AC-CM-P}$ are defined in the *PCI Express Base Specification*. Measurement is made over at least 10⁶ UI. 2.

3.

As measured with compliance test load. Defined as $2*|V_{TXD+} - V_{TXD-}|$. COMP resistance must be provided on the system board with 1% resistors. COMP resistors are to V_{SS}. PEG_ICOMPO, PEG_ICOMPI, PEG_RCOMPO are the same resistor 4.

5.

RMS value. 6. 7.

Measured at Rx pins into a pair of $50-\Omega$ terminations into ground. Common mode peak voltage is defined by the expression: max{|(Vd+ - Vd-) - V-CMDC|}. DC impedance limits are needed to guarantee Receiver detect. The Rx DC Common Mode Impedance must be present when the Receiver terminations are first enabled to onsure that the Receiver Detect occurs provely. Componentiation of this impedance can start immediately.

8.

9 The RX DC Common Mode Impedance must be present when the Receiver terminations are first enabled to ensure that the Receiver Detect occurs properly. Compensation of this impedance can start immediately and the 15 Rx Common Mode Impedance (constrained by RLRX-CM to 50 Ω ±20%) must be within the specified range by the time Detect is entered.
 Low impedance defined during signaling. Parameter is captured for 5.0 GHz by RLTX-DIFF.

7.10 Platform Environmental Control Interface (PECI) DC Specifications

PECI is an Intel proprietary interface that provides a communication channel between Intel processors and chipset components to external thermal monitoring devices. The processor contains a Digital Thermal Sensor (DTS) that reports a relative die temperature as an offset from Thermal Control Circuit (TCC) activation temperature. Temperature sensors located throughout the die are implemented as analog-to-digital converters calibrated at the factory. PECI provides an interface for external devices to read the DTS temperature for thermal management and fan speed control. For the PECI command set supported by the processor, refer to the appropriate processor Thermal and Mechanical Specifications and Design Guidelines for additional information (see Section 1.7).

7.10.1 DC Characteristics

The PECI interface operates at a nominal voltage set by V_{TT}. The set of DC electrical specifications shown in Table 7-11 is used with devices normally operating from a V_{TT} interface supply. V_{TT} nominal levels will vary between processor families. All PECI devices will operate at the V_{TT} level determined by the processor installed in the system. For specific nominal V_{TT} levels, refer to Table 7-6.

Symbol	Definition and Conditions	Min	Мах	Units	Notes ¹
V _{in}	Input Voltage Range	-0.150	V _{TT}	V	
V _{hysteresis}	Hysteresis	0.1 * V _{TT}	N/A	V	
V _n	Negative-Edge Threshold Voltage	0.275 * V _{TT}	0.500 * V _{TT}	V	
Vp	Positive-Edge Threshold Voltage	0.550 * V _{TT}	0.725 * V _{TT}	V	
Isource	High-Level Output Source ($V_{OH} = 0.75 * V_{TT}$)	-6.0	N/A	mA	
l _{sink}	Low-Level Output Sink ($V_{OL} = 0.25 * V_{TT}$)	0.5	1.0	mA	
I _{leak+}	High Impedance State Leakage to V_{TT} ($V_{leak} = V_{OL}$)	N/A	100	μΑ	2
I _{leak-}	High Impedance Leakage to GND $(V_{leak} = V_{OH})$	N/A	100	μΑ	2
C _{bus}	Bus Capacitance per Node	N/A	10	pF	
V _{noise}	Signal Noise Immunity above 300 MHz	0.1 * V _{TT}	N/A	V _{p-p}	

Table 7-11. PECI DC Electrical Limits

Notes:

1. V_{TT} supplies the PECI interface. PECI behavior does not affect V_{TT} min/max specifications.

2. The leakage specification applies to powered devices on the PECI bus.

7.10.2 Input Device Hysteresis

The input buffers in both client and host models must use a Schmitt-triggered input design for improved noise immunity. Use Figure 7-2 as a guide for input buffer design.

Figure 7-2. Input Device Hysteresis

-V _{TTD}			
-Maximum V _P	PECI High Range		
-Minimum V _P		-	
		Minimum Hysteresis	Valid Input Signal Range
-Maximum V _N			
-Minimum V _N	PECI Low Range		
-PECI Ground			J

8 Processor Land and Signal Information

8.1 **Processor Land Assignments**

The processor land-map quadrants are shown in Figure 8-1 through Figure 8-4. Table 8-2 provides a listing of all processor lands ordered alphabetically by pin name.

Not all signals are used by the processor. Table 8-1 lists the signals that are not used by the Intel Xeon processor 3400 series.

Table 8-1. Signals Not Used by the Intel[®] Xeon[®] Processor 3400 Series
